#### Abstract

In this paper, the results of an analysis of galaxy positions and magnitudes in European Southern Observatory (ESO) field 606 are presented. This $5^{\circ} \times 5^{\circ}$ field centred at $23.8 \mathrm{~h},-19^{\circ} .53$, contains 29313 galaxies with magnitudes $m_{\mathrm{F}}$ between 12.97 and 20.64. An automatic search of galaxy clusters and groups in the field was made using the Voronoi tessellation technique for two cases: firstly, for all galaxies in the field and, secondly, for galaxies within a magnitude limit of 18.3. We found 37 clusters of galaxies in the field for the first case, and nine clusters for the second case. There are seven Abell-Corwin-Olowin (ACO) clusters in this ESO field. The location of the identified structures on the celestial sphere suggests the existence of a possible galaxy supercluster in the field that covers a region measuring $4^{\circ} .8$ by $2^{\circ} .4$ centred at 23.841 h and $-20^{\circ} .44$. The largest clusters from both cases and five of the seven ACO clusters are in the region. The estimated size of the supercluster is $28 h^{-1} \times 14 h^{-1} \times 80 h^{-1} \mathrm{Mpc}$ for the supercluster $340 h^{-1} \mathrm{Mpc}$ distant.

Keywords: Galaxy clusters; Superclusters; Data analysis; Voronoi tessellation

## 1. Introduction

The Münster Red Sky Survey (MRSS) [1] is the observational basis for our studies involving searching for and investigating galaxy clusters and groups. The MRSS contains scans for 217 adjoining plates of the European Southern Observatory (ESO) Southern Sky Atlas R, which covers more than $5000 \mathrm{deg}^{2}$ and includes more than $5 \times 10^{6}$ galaxies. The catalogue is complete to a magnitude limit $m_{\mathrm{F}}=18.3$. Some plates have fainter magnitude limits with correspondingly greater degrees of completeness. The problem arising from different magnitude limits and their influence on the detection of galaxy clusters was discussed by Panko and Flin [2]. The difference between neighbouring plates vanishes for a limiting magnitude $m_{\mathrm{F}}=19.3$ for the galaxies considered.

The catalogue of galaxy clusters and groups compiled by Panko and Flin [3] (hereafter called the PF catalogue) was based on the analysis of a homogeneous portion of the MRSS. It includes 6188 structures, with at least ten galaxies in each. The extended version of the catalogue was

[^0]created for a magnitude limit $m_{\mathrm{F}}=19.3$. It includes more than 11000 structures. Analysis of structures detected below the magnitude limit of the whole MRSS survey permits us to obtain additional information about the clusters for individual ESO fields. This paper contains the results of a galaxy cluster search in ESO field 606 using two catalogues of structures: the PF catalogue and a catalogue based on all MRSS galaxies in the region.

## 2. Observational data and clusters search

ESO plate 606 covers the region with right ascension coordinates from 23.663 to 23.945 h and declinations from $-22^{\circ} .155$ to $-16^{\circ} .912$ and contains 29313 galaxies above a limiting magnitude of 20.64. The brightest galaxy in the field is at magnitude 12.97. There are only 6638 galaxies in the field with magnitudes less than the completeness limit of the MRSS of 18.3. So, about $80 \%$ of the galaxies in the field lie below the limits of the completed PF catalogue. We note that this situation is atypical of the MRSS and the PF catalogue. Two fields adjoining ESO field 606 contain galaxies with limiting magnitudes of about 18.6 [2].
We performed an analysis of local variations in the galaxy density for galaxies above the completeness limit of the MRSS and for the full list of galaxies in ESO field 606 using the Voronoi tessellation technique (VTT) for our clusters search [4]. The application of the VTT has been discussed by many researchers. Ramella et al. $[5,6]$ demonstrated in their papers that the technique is completely non-parametric and therefore sensitive to both symmetric and elongated clusters, allowing correct studies of non-spherically symmetric structures. Our search was made using the procedure kiang, which is the core of the Voronoi galaxy cluster finder (VGCF), an automatic package for identification of galaxy clusters in photometric galaxy catalogues [5].
The software searched for overdense regions in the field and then identified galaxies belonging to each overdense region. Two types of structure were identified as overdense regions: galaxy clusters and groups of galaxies. For each structure we obtained estimates for the radius and area and also the number of background galaxies. Structures with 50 and more members in the magnitude limits $m_{3}$ and $m_{3}+3$ were considered to be galaxy clusters, while others (less numerous) were termed galaxy groups. For each structure the covariance ellipse was inscribed, considering only galaxies within the above-mentioned magnitude limit. That allowed us to determine the ellipticity and the position angle of the structures by the standard method, described in [3].

## 3. Analysis and discussion

For the cluster search of galaxies with a limiting magnitude brighter than 18.3 we found nine groups and nine clusters of galaxies; three clusters have more than 100 members. The results of the search are presented in figure 1(a) as grey open circles. All structures are in the PF catalogue. When all galaxies taken from MRSS are considered, we find 22 groups and 37 clusters (figure 1(b)), with 13 clusters in this case containing more than 100 members. Both lists of galaxy clusters are given in appendix A as tables A2 and A3, respectively.

A comparison of the clusters present in the lists given in tables A2 and A3 shows that clusters in the PF catalogue are of larger size, while some of the structures from table A3 fully correspond to the structures in table A2. For structures with 50 or more members from table A2, only cluster 2392-1819 does not have an analogue in table A3, but at the same time three groups from the PF catalogue appear in table A3 as clusters. There are only seven

Figure 1. Galaxy clusters and groups (a) from the PF catalogue and (b) from the full list for ESO field 606 . The grey open circles represent individual galaxies belonging to the structures, and the black full circles show the centres of ACO clusters.

Abell-Corwin-Olowin (ACO) [7] galaxy clusters, and there are no clusters in the automated plate measurement (APM) catalogue [8] in this field. The centres of ACO galaxy clusters are depicted in figures 1 (a) and (b) as black full circles. All ACO clusters have counterparts in our lists. The counterparts of ACO clusters in both our lists are presented in table 1. The identifications, the radii in arcseconds estimated by the VTT, the number of galaxies in the magnitude limits $m_{3}$ and $m_{3}+3$, and $m_{\mathrm{F}}$ for the tenth-ranked cluster members are given for the newly found clusters.

The cluster 2393-2110 covers two ACO clusters, but ACO S1163 has a counterpart only in table A2. ACO clusters 2655, 4032 and 4045 are close to two or three clusters in table A3, as shown in figure 2 . The symbol sizes correspond to the relative sizes of the clusters. We conclude that the largest clusters have complex structures. Moreover, it is possible that these clusters are part of a complex structure of higher order. In the projection on the celestial sphere the structure appears as an ellipse with axes roughly $4^{\circ} .8$ by $2^{\circ} .4$ centred at $23.841 \mathrm{~h},-20^{\circ} .44$, with the position angle of its semimajor axis (measured clockwise from north) at about $51^{\circ}$. The ellipse contains seven of nine clusters from table A2 and 23 of 37 from table A3. In addition, five of seven ACO clusters in ESO field 606 are in the region.

When we count clusters located in the above region and considered as possible supercluster members in the ellipse, the difference beteen the magnitudes $m_{10}$ of the brightest and faintest

[^1]

Figure 2. A comparison of the positions for ACO clusters (crosses), for clusters from the PF catalogue (open circles) and for full list clusters from ESO field 606 (open squares). The possible supercluster is depicted by the dotted ellipse.
objects listed in table A2 is 1.00 , while it is 1.50 for the objects in table A3. The greater difference for objects in the table A3 obviously arises from the fainter magnitude limit of the list. The important point is that the difference between structure distances, as estimated from $m_{10}$, is rather small.

The distance classes, according to the classical papers by Abell [9] and Corwin [10], are estimated as classes 5-6 from the magnitude $m_{10}$ for table A2 clusters, excluding the largest, 2390-2048, and as classes 5-7 for table A3 clusters. The average magnitude values of 16.98 and 17.70 correspond to estimated distance limits of $280 h^{-1}-390 h^{-1} \mathrm{Mpc}$. We adopt a probable distance to the supercluster of $340 h^{-1} \mathrm{Mpc}$. Only one cluster, ACO 2655, of seven ACO clusters with measured $z=+0.1122$ [11] lies in ESO field 606. Unfortunately, it does not lie in the region discussed here. The magnitude of the tenth galaxy corresponding to this cluster in table A 3 is 17.23 , corresponding to distance class 6 . That corresponds to an estimated distance of $337 h^{-1} \mathrm{Mpc}$, very close to the estimate that we obtained above. In Friedmann-Lemaître-Walker-Robertson metrics for that distance, the angular size of the supercluster corresponds to $28 h^{-1} \times 14 h^{-1} \mathrm{Mpc}$, while the estimated depth for a magnitude of 1.00 is $80 h^{-1} \mathrm{Mpc}$.

The possible supercluster discussed here is not listed in the supercluster catalogue published by Einasto et al. [12], or in other supercluster lists.

## 4. Conclusions

From the analysis of galaxy positions and magnitudes in ESO field 606 we found a region with a higher concentration of galaxies that covers a region of sky measuring $4^{\circ} .8 \times 2^{\circ} .4$ centred at 23.841 h and $-20^{\circ} .44$. The region was detected both from galaxies with a brightness magnitude greater than 18.3 and from a full list of galaxies in the field considered. The region also contains five ACO clusters. We interpret this region as a possible new galaxy
supercluster that includes at least 23 galaxy clusters. The estimated dimensions of the supercluster are $28 h^{-1} \times 14 h^{-1} \times 80 h^{-1} \mathrm{Mpc}$ at a distance of $340 h^{-1} \mathrm{Mpc}$. There are no measured red shifts $z$ for galaxies in this region, which seem essential to demonstrate that it is truly a supercluster.

    ${ }^{\dagger}$ Member of a possible supercluster.
    ${ }^{*}$ Cluster 2393-2110 corresponds to two ACO clusters.
